System Request – Autonomous AI Agent Workflow Orchestration System

Project Sponsor: IT Operations Manager

Business Need:

There is an increasing trend among businesses that are beginning to leverage various AI tools for their operations. It becomes tedious to manage such AI tools separately. The current system will offer a single system where a number of AI agents will perform tasks together to achieve a common objective.

Business Requirements:

- Creation and management of various AI agents
- Set up an overall task for the system
- Splitting the overall task into small tasks
- Assignment of small tasks to the correct AI agents
- Execution of the small tasks either sequentially or simultaneously
- Monitoring the execution of the small tasks
- Re-execution of a failed small task
- Controlling the tools and data that the agents may access
- Seeking human intervention in case of crucial decisions

Business Value:

The system would save time and lessen manual efforts. The users will not have to individually control each AI agent. They will be able to set an overall goal, and the system will assist in managing the workload among the agents.

Conservative Estimation of Tangible Value Might Be as Follows:

- Less time spent on the management of AI task manually
- Fast execution of tasks
- Reduction in repetitive efforts by the employees

Specific Considerations or Constraints:

- It is important to keep the company's data secure and private.
- The AI agents should be restricted to the tools and data that are required.
- It should be possible for the users to manage the unsuccessful tasks.
- It must require human permission for significant decisions.
